Discrete Probabilistic Programming Languages II¹

Steven Holtzen s.holtzen@northeastern.edu

October 5, 2023

We have been filling in the PPL compilation picture which organizes different kinds of probabilistic programming languages:

- We now understand every component. Recall:
 - A language consists of syntax and semantics. We customarily
 give two kinds of semantics: a denotational semantics that describes the mathematical object associated with the program,
 and an operational semantics that tells us precisely how to
 compute that object. We typically prove something called "adequacy" that relates the denotational and operational semantics.
 - A compilation $L_1 \rightsquigarrow L_2$ is a procedure for translating programs written in language L_1 into L_2 that preserves semantics.
 - Language L_1 is more expressive than L_2 if we can efficiently compile any program from L_2 into L_1 but not vice versa;
 - We can compare tractability of languages based on their worstcase runtime complexity.
- Some bibliographic notes:
 - The process of compiling a Boolean formula into a tractable target is often called *knowledge compilation* in the literature [Darwiche and Marquis, 2002]. There are many tools for compiling formulae. Some knowledge compilation tools:
 - * c2d compiles from CNF to d-DNNF: http://reasoning.cs.ucla.edu/c2d/

¹ CS7470 Fall 2023: Foundations of Probabilistic Programming.

- * minic2d compiles from CNF to SDD: http://reasoning.cs. ucla.edu/minic2d/
- * rsdd compiles from Prop to SDD and BDD: https://github. com/neuppl/rsdd
- * sharpSAT compiles from CNF to d-DNNF [Muise et al., 2012]
- Disc is based on Dice [Holtzen et al., 2020]. There are other PPLs that work by knowledge compilation, such as ProbLog [Fierens et al., 2015, De Raedt et al., 2007], SPPL [Saad et al., 2021]. Historically, inference via compilation has been very effectively used in inference for graphical models [Chavira and Darwiche, 2008, Sang et al., 2005]
- What are some research questions in here?
 - Optimizing compilers for each stage.
 - New tractable target languages.
 - Compilation with performance guarantees.
 - Tools for making building these compilers.
- Disc: A simple discrete PPL
- Syntax:

```
e ::=
  | x \leftarrow e; e
                                     // q is a rational value
   | flip q
   | if e then e else e
   | return e
   | true | false
  | e ^ e | e V e | ¬ e |
  | ( e )
9 p ::= e
```

- Disc looks very similar to a standard functional programming language, but has two some interesting new keywords: flip, observe, and return
- flip θ allocates a new random quantity that is true with probability θ and false with probability $1 - \theta$
- return e turns a non-probabilistic quantity into a probabilistic one, i.e. return true is a probabilistic quantity that is true with probability 1 and false with probability o
- Example program and its interpretation:

```
1 x ← flip 0.5;
y \leftarrow flip 0.5;
3 return x ∧ y
```

This program outputs the probability distribution [true \mapsto 0.25, false $\mapsto 0.75$].

• Type system: terms can either be pure Booleans of type B or distributions on Booleans of type Dist(B). So, we have the following type definition:

$$\tau ::= \mathbb{B} \mid \mathsf{Dist}(\mathbb{B}). \tag{1}$$

• We define a typing judgment $\Gamma \vdash e : \tau$ that associates each term with a type. The typing context Γ is a map from identifiers to types.

$$\begin{split} \Gamma \vdash \mathsf{true} : \mathbb{B} & \Gamma \vdash \mathsf{false} : \mathbb{B} & \Gamma \vdash \mathsf{flip} \ \theta : \mathsf{Dist}(\mathbb{B}) \\ & \frac{\Gamma \vdash \mathsf{e} : \mathbb{B}}{\Gamma \vdash \mathsf{return} \ \mathsf{e} : \mathsf{Dist}(\mathbb{B})} \\ & \frac{\Gamma \vdash \mathsf{e}_1 : \mathsf{Dist}(\mathbb{B}) & \Gamma \cup [x \mapsto \mathbb{B}] \vdash \mathsf{e}_2 : \tau}{\Gamma \vdash x \leftarrow \mathsf{e}_1; \mathsf{e}_2 : \mathsf{Dist}(\tau)} \\ & \frac{\Gamma \vdash \mathsf{e}_1 : \mathbb{B} & \Gamma \vdash \mathsf{e}_2 : \tau & \Gamma \vdash \mathsf{e}_3 : \tau}{\Gamma \vdash \mathsf{if} \ \mathsf{e}_1 \ \mathsf{then} \ \mathsf{e}_2 \ \mathsf{else} \ \mathsf{e}_3 : \tau} & \frac{\Gamma \vdash \mathsf{e}_1 : \mathbb{B} & \Gamma \vdash \mathsf{e}_2 : \mathbb{B}}{\Gamma \vdash \mathsf{e}_1 \land \mathsf{e}_2 : \mathbb{B}} \end{split}$$

• This is often called a *monadic* type system [Moggi, 1991]; it waas introduced as a way of handling effects in purely functional languages. We won't get too into monads yet. If you're curious, see Ramsey and Pfeffer [2002].

Denotational semantics of Disc

- We will define our denotation on *closed terms*, i.e. terms with no free variables in them.
- There are two kinds of terms: probabilistic and pure terms. Probabilistic terms have type Dist(B), and pure terms have type B.
- The denotational semantics of pure terms is standard: they map closed terms to Boolean values. Examples of closed terms:

$$\label{eq:true} \begin{split} &\llbracket \mathsf{true} \rrbracket = \mathsf{true} \\ &\llbracket \mathsf{false} \rrbracket = \mathsf{false} \\ &\llbracket \mathsf{e}_1 \wedge \mathsf{e}_2 \rrbracket = \llbracket \mathsf{e}_1 \rrbracket \wedge \llbracket \mathsf{e}_2 \rrbracket \end{split}$$

• The denotational semantics of probabilistic terms maps closed terms to probability distributions, [e]: Bool $\rightarrow [0,1]$, and has the following inductive definition:

• Recall our notation for substitution e[v/x], which substitutes the variable x for value v. Here we define substitution to be *capture*avoiding. This concept is best illustrated by example. Considering the following program:

```
x \leftarrow true;
x ← false;
3 return true
```

What should this program return? Intuitively, it should return the distribution [false $\mapsto 1$, true $\mapsto 0$].

• A substitution e[v/x] is *capture-avoiding* if it only substitutes *free* occurrences of x with v in e. A variable is **free** if it does not occur inside of a binding. We can accomplish this with the following inductive description of substitution (here we show only a subset of the rules):

$$\begin{aligned} \mathsf{true}[x/v] &= \mathsf{true} & \mathsf{false}[x/v = \mathsf{false}] & x[x/v] &= v \\ \\ \frac{x \neq y}{y[x/v] = y} & (x \leftarrow \mathsf{e}_1; \mathsf{e}_2)[v/x] &= x \leftarrow \mathsf{e}_1[v/x]; \mathsf{e}_2 \\ \\ \frac{x \neq y}{(x \leftarrow \mathsf{e}_1; \mathsf{e}_2)[v/x] = y \leftarrow \mathsf{e}_1[v/x]; \mathsf{e}_2[v/x]} \end{aligned}$$

- In your project, we have implemented capture-avoiding substitution for terms in Disc for you.
- A simple example of the let-rule:

$$\llbracket x \leftarrow \mathtt{flip}\; \theta; \mathtt{return}\; x \rrbracket \, (\mathtt{true}) = \sum_{v \in \mathbb{B}} \, \llbracket \mathtt{flip}\; \theta \rrbracket \, (v) \times \llbracket \mathtt{return}\; v \rrbracket \, (\mathtt{true}) = \theta$$

- Compiling Disc to Prop
- Goal: give a semantics-preserving compilation → that compiles DISC to PROP.
- We want to define this relation to satisfy the following adequacy **condition**, assuming the program e → p:

$$\llbracket \mathbf{e} \rrbracket (\mathsf{true}) = \llbracket \mathbf{p} \rrbracket. \tag{2}$$

• Compilation relation:

$$\begin{array}{ll} \operatorname{true} \leadsto (\operatorname{true}, \varnothing) & \operatorname{false} \leadsto (\operatorname{false}, \varnothing) \\ x \leadsto (x, [x \mapsto 1/2, \overline{x} \mapsto 1/2]) & \frac{\operatorname{fresh} f}{\operatorname{flip} \theta \leadsto (f, [f \mapsto \theta, \overline{f} \mapsto 1 - \theta])} \\ & \frac{\operatorname{e}_1 \leadsto (\varphi, w) - \operatorname{e}_2 \leadsto (\varphi', w')}{x \leftarrow \operatorname{e}_1; \operatorname{e}_2 \leadsto (\varphi'[\varphi/x], w_1 \cup w_2)} \\ & \frac{\operatorname{e}_1 \leadsto (\varphi_1, w_1) - \operatorname{e}_2 \leadsto (\varphi_2, w_2)}{\operatorname{e}_1 \land \operatorname{e}_2 \leadsto (\varphi_1 \land \varphi_2, w_1 \cup w_2)} \\ & \frac{\operatorname{e}_1 \leadsto (\varphi_1, w_1) - \operatorname{e}_2 \leadsto (\varphi_2, w_2)}{\operatorname{e}_1 \land \operatorname{e}_2 \leadsto (\varphi_1, w_2)} \\ & \frac{\operatorname{e}_1 \leadsto (\varphi_1, w_1) - \operatorname{e}_2 \leadsto (\varphi_2, w_2) - \operatorname{e}_3 \leadsto (\varphi_3, w_3)}{\operatorname{if} \operatorname{e}_1 \operatorname{then} \operatorname{e}_2 \operatorname{else} \operatorname{e}_3 \leadsto ((\varphi_1 \land \varphi_2) \lor (\neg \varphi_1 \land \varphi_3), w_1 \cup w_2 \cup w_3)} \end{array}$$

• One thing to notice above: we have a new substitution rule $\varphi'[\varphi/x]$ that substitutes x with an arbitrary propositional formula φ in φ' . For example:

$$(x \lor y)[z \land w/x] = (x \land y) \lor y.$$

You can perform this operation directly on BDDs; it is called BDD composition.

- Now we are almost ready to state the semantics-preservation property of this compilation. We need one extra piece: environment substitution.
- Suppose $\Gamma \vdash$ e. A substitution $\gamma \in \llbracket \Gamma \rrbracket$ gives an assignment to every free variable in e. We use the notation $e[\gamma]$ to denote performing the substituting of all variables in γ in e, i.e.:

$$e[\{[v_1/x_1,v_2/x_2,\ldots,v_n/x_n]\}] = e[v_1/x_1][v_2/x_2]\ldots[v_n/x_n].$$

Additionally, note that we can apply this same substitution notation to propositional formulae, i.e. $\varphi[\gamma]$ is also well-defined according to the above description.

Theorem 1. Assume $\Gamma \vdash e$ and $e \leadsto p$. Then, for any substitution $\gamma \in \llbracket \Gamma \rrbracket$, is is the case that $\llbracket e[\gamma] \rrbracket$ (true) = $\llbracket p[\gamma] \rrbracket$

Proof. The proof is on structural induction on terms in e.

The base case for flip is simple but a good place to start. Assume flip $\theta \leadsto (f, [f \mapsto \theta, \overline{f} \mapsto 1 - \theta])$. Then,

$$\llbracket \texttt{flip} \ \theta \rrbracket \ (\texttt{true}) = \theta = \left\llbracket (f, [f \mapsto \theta, \overline{f} \mapsto 1 - \theta]) \right\rrbracket.$$

The critical case is the inductive step for binding. Inductive hypothesis: assume that $e_1 \rightsquigarrow (\varphi_1, w_1)$ and $e_2 \rightsquigarrow (\varphi_2, w_2)$, and that for any well-typed substitution γ it is the case that:

- $\llbracket \mathsf{e}_1[\gamma] \rrbracket (\mathsf{true}) = \llbracket \varphi_1[\gamma] \rrbracket$
- $\llbracket e_2[\gamma] \rrbracket (\mathsf{true}) = \llbracket \varphi_2[\gamma] \rrbracket$

We need to show that $[x \leftarrow e_1; e_2]$ (true) = $[\varphi_2[\varphi_1/x], (w_1 \cup w_2)]$. **TODO**; if you want, you can take a peek at Holtzen et al. [2020]

• Question: Is this an efficient compilation? Yes.
